

ADC

Connect grounds at ADC

Accepts 5V digital input on 3.3V VDD

POWER

LP5907 allows output capacitors placed far from LDO

Boring LDO internally set to 3.3V output.
(the LP5907 is pretty cool but the implementation is boring)

INTERFACE

Test Points

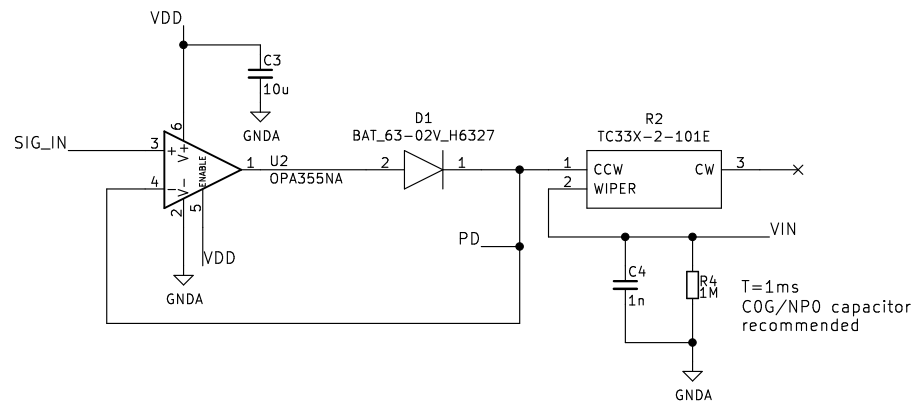

Connectors

Some spots around the board that might be useful for debugging but hard to reach otherwise.

"Not connected" pins are I2C.

Notes:
The ADC itself pulls 2mA.
The Pi has configurable pull up/down resistors. As a result, no output resistors are included in this design.
Johnson noise equivalent to the LSB would be $>1M\Omega$.

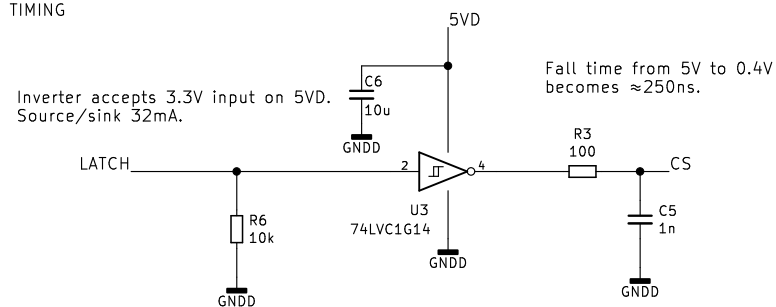

ANALOG INPUT

$T=1ms$
COG/NPO capacitor recommended

Peak detect with adjustable R_s

CS TIMING

Inverter accepts 3.3V input on 5VDD.
Source/sink 32mA.

Fall time from 5V to 0.4V becomes $\approx 250ns$.

CS is delayed inverted latch.

Rev Notes:
Removed ADC buffer, switched to single op amp
Switched to RC CS delay circuit
Updated to KiCad 5, updated component libraries
